## **ABSTRACT**

### **USING THE KDJ AS A TRADING STRATEGY ON BIOTECH COMPANIES**

**by  
Shijie Zha**

Mean Reversion is the most commonly used model in quantitative trading. This model is associated with several factors, like ma5 and ma10 line. These factors are the most significant in stock markets. However, the disadvantages of this model are lag and inaccuracy.

In this research, we get the historical and current stock data by web crawler, analyze the quantitative data and build a new model involved with the KDJ. Taking biotech companies marketed in the United States and B-share marketed in China as the research subjects, the result shows increased profits compared with the Mean Reversion model. It also shows that as long as we clearly understand the relationship between the turnover and fluctuation of share price, we can find the trading signals more accurately and generate more profit.

## **BIOGRAPHICAL SKETCH**

**Author:** Shijie Zha

**Degree:** Master of Science

**Date:** May 2016

### **Undergraduate and Graduate Education:**

- Master of Science in Bioinformatics,  
New Jersey Institute of Technology, Newark, NJ, 2016
- Bachelor of Science in Biotechnology,  
University of Florence, Florence, Italy, 2013

**Major:** Bioinformatics

I dedicate this work to my loved family and the people who helped me.

## **ACKNOWLEDGMENT**

I would like to express my sincere gratitude to my thesis advisor Dr. Zhi Wei, for this long term support of my study and research, not only in the thesis, but also in my whole one year's learning in NJIT. I also would like to thank the committee members Prof. Usman Roshan and Prof. Jason Wang, for their excellent teaching and guidance. Besides, I would like to thank Jie Zhang, Tian Tian, Weiting Xu, for their help and encouragement.

Finally, I want to thank my parents, for their supporting me all through my studies in NJIT.

# CHAPTER 1

## INTRODUCTION

### 1.1 Background Information

Biotechnology affects people's lives. With the increasingly rapid technological development, the impact is even greater. In our daily life, we can see the life with the help of biotechnology, such as medicine, biotechnology, drug effect, less side effect, low toxicity, high safety. In terms of Food, create new varieties to enrich our table, as well as environmental protection, transfer of pollutants in the wastewater using microbial life activities, so that the waste water to be purified. With the development of biological technology, the effect will be more and more. In the future, the development of biological technology development will certainly be more mature, do more benefit to our life. Even Though unique financial challenges faced by biotechnology companies developing therapeutics have contributed to the creation of a highly sensitive market, where stock prices are capable of great fluctuation [2]. The evolution of modern biotechnology is continuing at a rapid pace, so it can be a very worthwhile investment.

Most companies listed on Chinese exchanges will offer two shares classes: A-shares and B-shares. A-Shares on the Shanghai and Shenzhen stock exchanges refer to those that are traded in CNY. In general, foreign individuals are not allowed to directly invest in A-shares as CNY is not a convertible currency and the Capital Account of China is not open yet, while B-shares are quoted in foreign currencies (such as the U.S. dollar) and are open to both domestic and foreign investment (provided that locals set up a foreign currency account). The evidence shows foreign institutional investors are the

main participants in B-share markets [1]. The regular operating hours for the Shanghai Stock Exchange (SSE), Shenzhen Stock Exchange (SZSE), are Monday through Friday from 9:30 a.m. to 11:30 a.m. GMT+08, and 13:00 p.m. to 15:00 p.m. GMT+08.

Finally, we applied our strategy on biotech companies that are marketed in United States and B-share marketed in China to see whether the strategy is suitable.

## CHAPTER 2

### DATA SET

#### 2.1 Data Description

We want to get the biotech company data of recent 100 trading day. In stock market, they are daily candlestick data, one minute candlestick data and transaction's detail. A daily candlestick is based on the open price, the intraday high and low, and the close. The column names of daily candlestick are open, high, close, low, volume, p\_change, ma5 (average price of 5 trading days), ma10 (average price of 10 trading days), ma20 (average price of 20 trading days), v\_ma5 (average volume of five trading days), v\_ma10 (average volume of 10 trading days), v\_ma20 (average volume of 20 trading days), turnover. One minute Candlesticks which is based on the open, the high, the low, and the close price in one minute. The column names of one minute candlestick are date, time, open, high, low, close, volume, amount. Transaction's detail describes the volume traded in a certain price, and the column names are time, price, change, volume, amount, type (Buy or Sell). Every day there are 240 transactions. There are 16322 observations every stock. The monetary unit is US dollar. The format of the data is data frame. In total, there are 300 stocks of Biotech Company and 45 stocks in B-market.

## 2.2 Method for Getting Dataset

We use web crawler to get the daily and transaction's detail data by using Python and get the one minute data using tdx software.

**Table 2.1** Example of Daily Candlestick Data

Date	Open	High	Low	Close	Volume	Amount
2015/10/29	39.98	40.41	39.20	39.95	1796255	71733744.00
2015/10/30	40.29	40.29	38.90	39.29	1729301	68646616.00
2015/11/02	38.10	40.88	38.08	40.02	3104060	123307096.00

14:59:20	6.05	0.01	4	2424	B

## 2.3 Method for Getting Every Minute's Data

We use software of securities company(Tong Da Xin) to get the every minute's data which can be extracted by batch, and the format is the following:

**Table 2.3** Example of Every Minute's Data

Date	Time	Open	High	Low	Close	Volume	Amount
2015/10/29	0931	39.98	39.98	39.30	39.55	17600	699213.00

2015/10/29	0935	39.75	40.20	39.75	40.18	80100	3198831.00

## CHAPTER 3

### IMPLEMENTATION

#### 3.1 Quantitative and Qualitative Analysis

##### 3.1.1 Daily Random Indicator KDJ Value

There are a total of three lines standing for random indicator in the stock, namely K line, D line and the J line. Random indicator not only considers the highest price, the lowest price in the calculation period, but also takes into account of the random amplitude in the course of the fluctuation of stock price. Therefore, researchers always think that random indicator can more truly reflect the volatility of stock price, and it plays an important role in prompting [3].

To calculate the k value, d value and j value, we need to calculate the rsv first:

$rsv = (\text{Close price} - \text{Low}) / (\text{High} - \text{Low}) * 100$ , which Close price is the price of last second in one minute, High represents the highest price in the last 9 days, and low represents the lowest price in the last 9 days,

For the first day of our data, we use these formulas to calculate the k value, d value and j value:

$$k = 2/3 \times 50 + 1/3 \times rsv \quad (3.1)$$

$$d = 2/3 \times 50 + 1/3 \times k \quad (3.2)$$

$$j = 3 \times k - 2 \times d \quad (3.3)$$

For the other days in our data, we use these formulas to calculate the k value, d value and j value:

$$k = 2/3 \times k^* + 1/3 \times rsv \quad (3.4)$$

$$d = 2/3 \times d^* + 1/3 \times k \quad (3.5)$$

$$j = 3 \times k - 2 \times d \quad (3.6)$$

$k^*$  represents the k value from last day, and  $d^*$  represents the d value from the last day. When High is equal to Low in denominator in this formula  $rsv = (\text{Close price} - \text{Low}) / (\text{High} - \text{Low}) \times 100$ , then rsv is NA, so we can't calculate the k value. Then we get the k value from k value from last day.

After we calculate the k value, d value, and j value, we can draw the kdj line. In order to know the accuracy of these calculations, we compare our kdj to the securities company's kdj in the software.

**Figure 3.1.1** Example of daily kdj line from 09/2015 to 02/2016.

### 3.1.2 K, D, J Value of Every Minute

To calculate the k value, d value and j value, we need to calculate the rsv first:

$$rsv^1 = (\text{Close price} - \text{Low}) / (\text{High} - \text{Low}) * 100$$

Close price is the price of last second in one minute, and High represents the highest price in the last 9 minutes, and low represents the lowest price in the last 9 minutes,

For the first minute, we use these formulas to calculate the  $k^1$  value,  $d^1$  value and  $j^1$  value:

$$k^1 = 2/3 \times 50 + 1/3 \times rsv^1 \quad (3.7)$$

$$d^1 = 2/3 \times 50 + 1/3 \times k^1 \quad (3.8)$$

$$j^1 = 3 \times k^1 - 2 \times d^1 \quad (3.9)$$

For the other minutes, we use these formulas to calculate the  $k^1$  value,  $d^1$  value and  $j^1$  value:

$$k^1 = 2/3 \times k^{1*} + 1/3 \times rsv^1 \quad (3.10)$$

$$d^1 = 2/3 \times d^{1*} + 1/3 \times k^1 \quad (3.11)$$

$$j^1 = 3 \times k^1 - 2 \times d^1 \quad (3.12)$$

$k^1*$  represents the  $k^1$  value from last minute, and  $d^1*$  represents the  $d^1$  value from the last minute. When High is equal to Low in denominator in this formula  $rsv^1 = (\text{Close price} - \text{Low}) / (\text{High} - \text{Low}) * 100$ , so  $rsv^1$  is NA. If we can't calculate the  $k^1$  value, we take get the  $k^1$  value from  $k^1$  value from last minute.

**Figure 3.1.2** Example of one-minute kdj line from 01/04/2016 to 01/04/2016.

### 3.1.3 Moving Average

The most popular indicator is the moving average. This shows the average price over a period of time. For a 30-day moving average you add the closing prices for each of the 30 days and divide by 30. The most common averages are 20, 30, 50, 100, and 200 days. Longer time spans are less affected by daily price fluctuations. A moving average is plotted as a line on a graph of price changes. When prices fall below the moving average they have a tendency to keep on falling. Conversely, when prices rise above the moving average they tend to keep on rising [5]. To calculate the moving average of one stock, we

use this formula:  $MA(n) = (C1+C2+C3+C4+C5+....+Cn)/n$ , in which C is the close price of one day, n is the number of recent trading days. Here we calculate the MA(5),MA(10).

**Figure 3.1.3** Example of ma5, ma10 and price lines from 09/2015 to 02/2016.

### 3.2 Trading Simulation

Good prediction precision/accuracy does not guarantee a high investment return [3], so we don't develop an algorithm to predict the fluctuation of the share price. However, we try to figure out a strategy of trading which may be used to higher profits than buy-and-hold strategy.

A trading simulation was developed in an effort to further examine if the neural network models could practically be used to generate higher profits than those earned either by employing the traditional regression model or by simply following a buy-and-hold (passive) investment strategy.

Here, we define several key points at which we will perform different actions when these key points appear or disappear.

When the K-line, D-line, J-line up-cross each other, and the K, D, J values are less than 30, and we define that intersection is a golden cross of KDJ. This so-called golden cross is seen as a signal of oversold. When a golden cross appears, we buy the stock in next minute, which is called buy point.

When the K-line, D-line, and J-line down-cross each other, and the K, D, J values are greater than 70, then we define that intersection is a death cross of KDJ. This so-called death cross is seen as a signal of overbought. When a death cross appears, we sell the stock in next minute, which is called sell point. Actually, in this model, we don't sell the share second the death point, but second the rate of return, which is 120%. For example, after we buy the stock at 1 dollar, we sell the stock at the price of  $1 \times 120\%$ .

About when we enter the market, there are two key points. First, after the day-kdj appears the golden points, we enter the market.

Second, when the 5-day simple moving average of price is below the 10-day moving average, we don't buy any share. If we have bought several shares in the previous trading day, we also sell the whole share when MA5 is below MA10. However, when the 5-day simple moving average of price is above the 10-day moving average, we buy the share.

A trading simulation was developed to further examine if this strategy could be used to generate higher profits [4].

## CHAPTER 4

### RESULTS

We applied this strategy on bio-tech companies marketed in the United States to see whether this strategy is available in United States, and the results show below.

**Table 4.1** Results of Strategy Involved with Moving Average

From Table 4.1, 62% of shares are profitable, but this percentage is unsatisfactory. After reviewing most of the trading records, we find this strategy has some defects. Because ma5 takes a few days to down-cross the ma10, this lag will influence the trading. When the share price keeps on dropping in two days, the ma5 and ma10 will not react quickly enough. Because of the lag of the ma5 and ma10, we developed another strategy which can response quickly and lead to loss less money lost.

When a golden cross appears, the price of share will rise, so we buy the share in

three days after golden cross appears, and sell them in the next three days. This interval of transaction will be finished in 5 days. After 5 days, the probability of dropping of the share price is much greater than the increasing. However, if the price still rise, the golden cross will appear again, we can repeat the transaction described above.

We applied this strategy on bio-tech companies marketed in the United States to see whether this strategy is availability in United States, and the results are show below.

From Table 4.2, 80% of the stocks are profitable. Even though 147 share prices decline, they are still profitable. Here is no doubt that our strategy is better than buy-and-hold (passive) strategy. To optimize the strategy or improve the accuracy of the investment, we can select the share before trading, which may make us more profitable and reduce the risk. A large body of evidence has accumulated suggesting that stock returns are predictable by means of publicly available information on a number of

financial and macroeconomic variables with an important business cycle component [6]. Here we didn't select the share, but traded with total 300 shares. The furthermore study is to select the stock second fundamental analysis, policy regulation, and message of rumors.

In addition, there are 20% deficit stocks, which may be caused by several situations. First, the share prices kept on declining in three month and with little fluctuation of share prices. At this situation, we definitely would loss money. As I described above, we can avoid buying these shares by fundamental analysis. Second, there is a certain probability the golden-cross is false or not accurate, which may mislead us to buy the shares. After buying the shares second the false golden-cross, the price will not increase, but drop, which means we lose money.

**APPENDIX A**  
**B-SHARE MARKET**

We also performed our strategy on B-share market in China. From Table 4.3, we find 37 stocks are profitable. Even though share prices dropped, 12 stocks are still profitable.

## APPENDIX B

### CODE FOR TRADING

#### B.1 Code for Getting The Daily Data

In this APPENDIX, we use the code in Table B.1 to get the daily data.

**Table B.1** Code for Getting The Daily Data

---

```
import tushare as ts

import sys

reload(sys)

sys.setdefaultencoding('utf8')

error = open('error.txt', 'w')

stock_code = open("stock_code.txt", "r")

sc = stock_code.read()

stock_code.close()

sc = sc.split('\n')

for i in sc:

    try:

        df = ts.get_stock_basics()

        start_date = df.ix[i]['timeToMarket']

        start_date = str(start_date)

        sd=start_date[:4] + '-' + start_date[4:6] + '-' +start_date[6:8]

        stock = ts.get_h_data(i, start=sd, end='2015-12-18')

        name_of_file = '%s.xlsx'%i

        stock.to_excel(name_of_file)

    except Exception, e:
```

**Table B.1 (continued)** Code for Getting The Daily Data

---

```
print "error%s"%i
    error.write(str(i)+'\n')
error.close()
```

## B.2 Code for Getting Transaction Detail

In this APPENDIX, we use the code in Table B.2 to get transaction detail.

**Table B.2** Code for Getting Transaction Detail

---

```
import tushare as ts

import sys

reload(sys)

sys.setdefaultencoding('utf8')

error = open('error.txt', 'w')

stock_code = open("stock_code.txt","r")

sc = stock_code.read()

stock_code.close()

sc = sc.split('\n')

for i in sc:

    try:

        df = ts.get_stock_basics()

        start_date = df.ix[i]['timeToMarket']

        start_date = str(start_date)

        print i

        sd=start_date[:4] + '-' + start_date[4:6] + '-' +start_date[6:8]

        stock = ts.get_tick_data (i, start=sd, end='2015-12-18')

        name_of_file = '%s.xlsx'%i

        stock.to_excel(name_of_file)

    except Exception, e:

        print "error%s"%i

        error.write(str(i)+'\n')

error.close()
```

### B.3 Code for Daily KDJ

In this APPENDIX, we use the code in Table B.3 to calculate daily KDJ.

**Table B.3** Code for Daily KDJ

---

```
setwd("/Users/apple/Workspace/day_price")

library(ggplot2)

library(reshape2)

library(dplyr)

day <- read.table("SZ300357.txt", header = T, skip = 1, stringsAsFactors = F,
                 col.names = c("date", "open", "high", "low", "price", "vol", "value"), fill = T)

day <- day[-(nrow(day)),]

day$h_d <- NA

day$l_d <- NA

for(i in 9:nrow(day)){
  day$h_d[i] <- max(day$high[(i-8):i])
  day$l_d[i] <- min(day$low[(i-8):i])
}

day <- na.omit(day)

day$rsv_d <- NA

day$k_d <- NA

day$d_d <- NA

day$j_d <- NA

day$rsv_d[1] <- (day$price[1] - day$l_d[1]) / (day$h_d[1] - day$l_d[1]) * 100

day$k_d[1] <- 2/3 * 50 + 1/3 * day$rsv_d[1]
```

**Table B.3 (continued)** Code for Daily KDJ

---

```
day$d_d[1] <- 2/3 *50 + 1/3 *day$k_d[1]

day$j_d[1] <-3*day$k_d[1] -2*day$d_d[1]

for(i in 2:dim(day)[1]) {

  day$rsv_d[i] <- (day$price[i] -day$l_d[i])/(day$h_d[i] -day$l_d[i])*100

  if (is.na(day$rsv_d[i])){
